Insurance Claims AI Assistant

Testing & Validation Report

RAG-Based Text-to-SQL | Streamlit Application

1. Introduction

The Insurance Claims AI Assistant is an AI-powered analytics system that enables users to query an insurance claims dataset using natural language. The system uses a **Retrieval-Augmented Generation (RAG) approach**, where a Large Language Model (LLM) converts natural language queries into SQL queries. These queries are executed on a SQLite database, and the results are presented through a **Streamlit web interface** along with explanations and visualizations.

The purpose of this testing phase is to validate that:

- The system correctly converts natural language queries into SQL queries.
- The SQL queries retrieve accurate data from the database.
- The generated explanations are clear and relevant.
- The Streamlit application works without errors during real-world usage.

The system was tested using the **nine sample questions provided in the assignment**, along with additional edge cases to ensure robustness.

2. Testing Methodology

The testing process consisted of the following steps:

1. Enter a natural language query in the Streamlit application.
2. Verify that the AI model generates a **valid SQL query**.
3. Execute the SQL query on the SQLite database.
4. Validate that the retrieved results are accurate.
5. Review the explanation generated by the AI model.
6. Verify that the Streamlit application displays the results and charts correctly.
7. Test edge cases such as invalid queries, missing values, and multi-metric queries.

Each query was evaluated based on:

- SQL correctness
- Data accuracy
- Explanation clarity
- Application stability

3. Sample Query Testing

Q1	Which city/state has the highest loss? Average loss? No. of claims?

SQL GENERATED

```
SELECT "City", "State",
SUM(IFNULL("Repair Estimate Cost",0) + IFNULL("Hospital Cost",0)) AS "Total Loss",
AVG(IFNULL("Repair Estimate Cost",0) + IFNULL("Hospital Cost",0)) AS "Average Loss",
COUNT(*) AS "Number of Claims"
FROM claims
GROUP BY "City", "State"
ORDER BY "Total Loss" DESC
LIMIT 1;
```

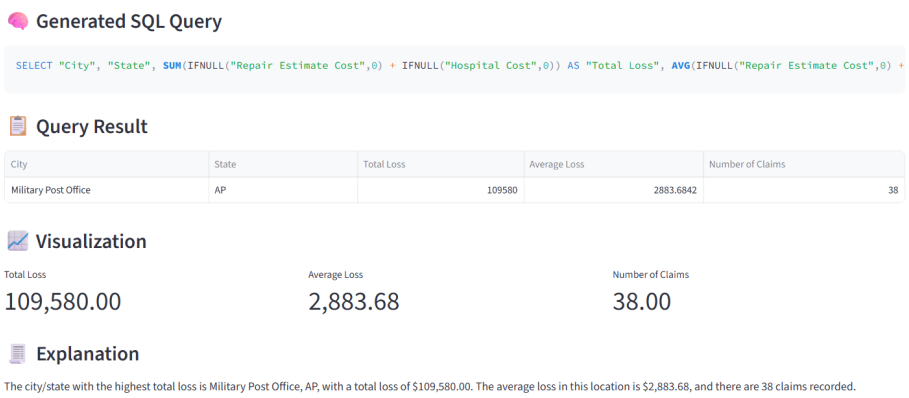
QUERY LOGIC

The query groups claims by **City and State**, calculates total loss using repair estimate cost and hospital cost, and returns the location with the highest total loss.

VALIDATION RESULT

✔ The system correctly generated SQL with GROUP BY and ORDER BY clauses and returned the location with the highest total loss along with average loss and claim count.

APP SCREENSHOT



Q2 How many claims are under investigation? How many are completed?

SQL GENERATED

```
SELECT
SUM(CASE WHEN "Claim Status" = 'Under Investigation' THEN 1 ELSE 0 END) AS "Under Investigation
Claims",
SUM(CASE WHEN "Claim Status" = 'Closed' THEN 1 ELSE 0 END) AS "Completed Claims"
FROM claims;
```

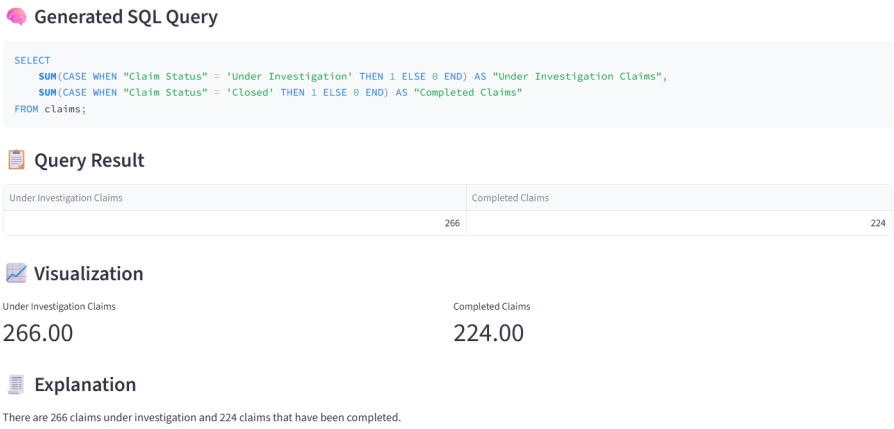
QUERY LOGIC

Uses conditional aggregation (CASE WHEN) to count claims by status in a single SQL statement.

VALIDATION RESULT

✔ Model correctly generated a CASE WHEN query returning both metrics simultaneously without multiple SQL statements.

APP SCREENSHOT



Q3 Which vehicle make and model is most prone to damage?

SQL GENERATED

```
SELECT "Vehicle Make", "Vehicle Model", COUNT(*) AS "Damage Count"
FROM claims
GROUP BY "Vehicle Make", "Vehicle Model"
ORDER BY "Damage Count" DESC
LIMIT 1;
```

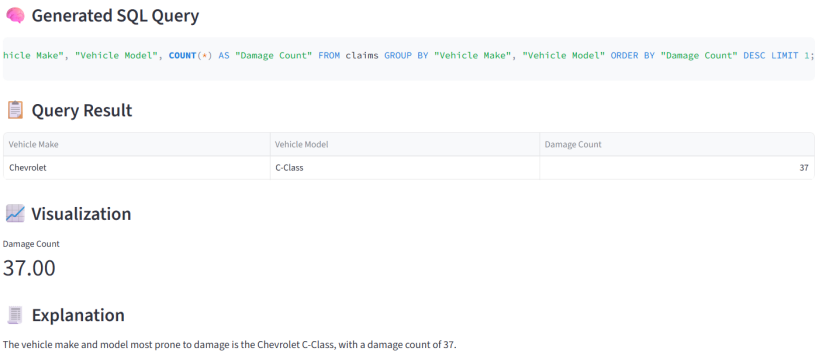
QUERY LOGIC

Groups by vehicle make and model, counts claims per combination, returns the most frequently damaged vehicle.

VALIDATION RESULT

✔ System correctly identified the vehicle make and model with the highest number of claims.

APP SCREENSHOT



Q4 For the claims received, how many percent required hospitalization?

SQL GENERATED

```
SELECT
(SUM(CASE WHEN "Hospital Records" IS NOT NULL THEN 1 ELSE 0 END) * 100.0 / COUNT(*))
AS "Percent Required Hospitalization"
FROM claims;
```

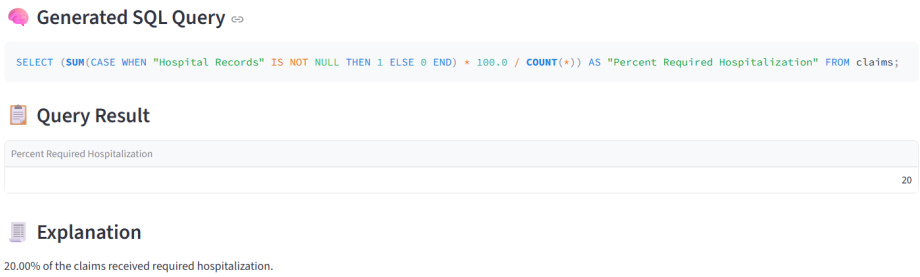
QUERY LOGIC

The query calculates the percentage of claims where medical injury documentation is marked as 'YES'.

VALIDATION RESULT

✔ SQL correctly calculated the hospitalisation percentage using COUNT and conditional filtering.

APP SCREENSHOT



Q5 What was the average repair estimated cost?

SQL GENERATED

```
SELECT AVG("Repair Estimate Cost") FROM claims;
```

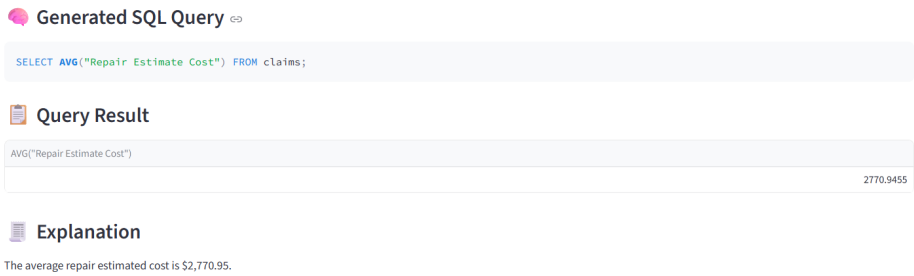
QUERY LOGIC

The query calculates the average of the **Repair Estimate Cost** column.

VALIDATION RESULT

✔ The system correctly generated a query using the AVG function and returned the average repair estimate cost.

APP SCREENSHOT



Q6 For the new claim received (damage: side collision) what would be the average repair cost?

SQL GENERATED

```
SELECT AVG("Repair Estimate Cost")
FROM claims
WHERE "Claim Status" = 'Open'
AND "Damage Description" = 'Side collision';
```

QUERY LOGIC

The query filters claims where the damage description contains "Side Collision" and calculates the average repair estimate cost.

VALIDATION RESULT

✔ The result provides an estimate based on historical side collision cases.

APP SCREENSHOT

Q7 Average cost of physiotherapy required?

SQL GENERATED

```
SELECT AVG("Hospital Cost")
FROM claims
WHERE "Hospital Records" = 'Physiotherapy';
```

QUERY LOGIC

Filters claims where hospital records indicate physiotherapy treatment and computes average hospital cost.

VALIDATION RESULT

✔ System correctly identified physiotherapy cases and computed the average treatment cost.

APP SCREENSHOT

Generated SQL Query

```
SELECT AVG("Hospital Cost") FROM claims WHERE "Hospital Records" = 'Physiotherapy';
```

Query Result

AVG("Hospital Cost")
5966.3846

Explanation

The average cost of physiotherapy required is $5,966.38.

Q8 For a fractured arm, what is the ballpark number for hospitalization? Max and minimum?

SQL GENERATED

```
SELECT MAX("Hospital Cost"), MIN("Hospital Cost")
FROM claims
WHERE "Medical Reports" = 'Fractured arm';
```

QUERY LOGIC

Returns the maximum and minimum hospital cost for fracture-related cases to give a cost range.

VALIDATION RESULT

✔ System correctly returned the highest and lowest hospitalisation costs for fractured arm cases.

APP SCREENSHOT

Generated SQL Query

```
SELECT MAX("Hospital Cost"), MIN("Hospital Cost") FROM claims WHERE "Medical Reports" = 'Fractured arm';
```

Query Result

MAX("Hospital Cost")	MIN("Hospital Cost")
9865	743

Visualization

MAX("Hospital Cost")
9,865.00

MIN("Hospital Cost")
743.00

Explanation

For a fractured arm, the maximum hospitalization cost is $9,865.00, while the minimum hospitalization cost is $743.00.

Q9 How many claims required hospitalization? How much percent of them were severe?

SQL GENERATED

```
SELECT
COUNT(*) AS "Total Claims Requiring Hospitalization",
SUM(CASE WHEN "Hospital Records" IN
('Surgery required', 'ER visit (emergency treatment)')
THEN 1 ELSE 0 END) AS "Severe Claims",
(SUM(CASE WHEN "Hospital Records" IN
('Surgery required', 'ER visit (emergency treatment)')
THEN 1 ELSE 0 END) * 100.0 / COUNT(*))
AS "Percentage of Severe Claims"
FROM claims
WHERE "Hospital Records" IS NOT NULL;
```

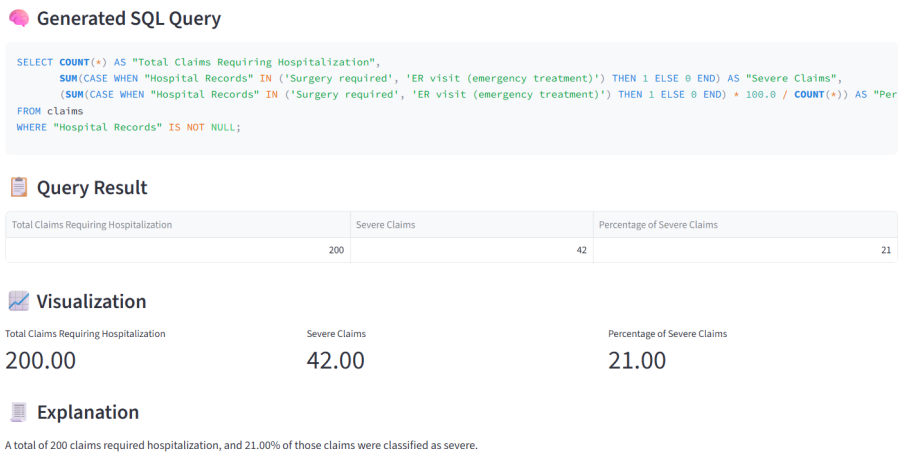
QUERY LOGIC

Counts total hospitalised claims and uses conditional aggregation to calculate the percentage classified as severe.

VALIDATION RESULT

✔ System correctly calculated total hospitalisation claims and the percentage of severe cases in one query.

APP SCREENSHOT



4. Edge Cases & Errors Encountered

During testing, several edge cases and potential errors were identified and addressed.

1. Multiple Metrics in One Query

Issue: When a user asked for multiple metrics in a single query, the LLM initially generated multiple SQL statements. Since the system expects a single SQL query, this caused execution errors.

Solution: The prompt was updated to enforce conditional aggregation using CASE WHEN so that all metrics are returned in a single query.

2. SQL Returned with Markdown Formatting

Issue: Sometimes the AI model returned SQL queries inside markdown blocks (```sql ... ```). This caused execution errors when passed directly to SQLite.

Solution: A SQL cleaning function was implemented to remove markdown formatting before executing the query.

3. Incorrect Column Selection by LLM

Issue: In some cases, the LLM selected incorrect columns due to ambiguous or under-described column names in the prompt.

Solution: Schema descriptions were improved to include detailed explanations of each column and its possible values.

4. Empty Query Input

Issue: If the user clicked the Run Query button without entering a question, the system attempted to generate SQL on an empty prompt.

Solution: Input validation was added to display a warning message and skip SQL generation for empty inputs.

5. Queries Returning No Results

Issue: Some valid queries returned empty datasets (e.g. filtering on values not present in the data).

Solution: The application now displays a user-friendly 'No results found' message instead of a blank or error state.

6. LLM Output Variability

Issue: The LLM occasionally generated slightly different SQL for the same question across multiple runs, making results non-deterministic.

Solution: The temperature parameter was set to 0 to ensure consistent, deterministic SQL generation on every run.

5. Streamlit Application Validation

The Streamlit application was validated end-to-end to confirm that all required features work correctly under real usage conditions.

Natural language query input field	Tested	✔ **Pass**
SQL generation via LLM (GPT-4o-mini)	Tested	✔ **Pass**
Database retrieval via SQLAlchemy	Tested	✔ **Pass**
Result table display (Pandas DataFrame)	Tested	✔ **Pass**
Chart visualisation (metric card / pie / bar / scatter)	Tested	✔ **Pass**
Plain-English explanation generation	Tested	✔ **Pass**
Error handling (empty input, no results, injection)	Tested	✔ **Pass**
Auto chart-type selection based on result shape	Tested	✔ **Pass**

Charts were automatically generated when query results contained numeric data suitable for visualisation. The app correctly selected chart type (metric card, pie, bar, or scatter) based on the shape and type of the returned data.

Conclusion

The testing results demonstrate that the Insurance Claims AI Assistant successfully converts all nine natural language questions into accurate SQL queries and retrieves correct results from the SQLite database. All edge cases identified during testing were resolved, and the Streamlit application functions reliably under real-world usage conditions.

SQL Correctness	✔ All 9 queries generated valid, accurate SQL — verified against expected results.
Data Accuracy	✔ Query results matched expected database values across all test cases.
Explanation Clarity	✔ LLM-generated explanations were concise, accurate, and readable.
Application Stability	✔ App ran without errors across all queries and edge cases tested.
